TITLE: Modification of skeletal nickel catalyst with transition metal admixtures.
Part 2: Electrolytic oxidation of hydrogen and catalytic hydrogenation on skeletal nickel-chromium alloys

SOURCE: Zhurnal fizicheskoy khimii, v. 40, no. 8, 1966, 1758-1765

TOPIC TAGS: nickel alloy, chromium alloy, hydrogenation, anodic oxidation

ABSTRACT: The paper examines the effect of adding chromium to a skeletal nickel catalyst containing 50 wt. % Al during the electrolytic oxidation of hydrogen on ceramic diffusion electrodes and in a catalytic hydrogenation reaction. Alloying with chromium was found to lower the activity of skeletal nickel catalyst during the electrooxidation of hydrogen in alkaline electrolytes and during hydrogenation of potassium maleate and o-nitrophenol. The hydrogenation rate decreases upon addition of small amounts of Cr, then increases, reaching a maximum on a catalyst containing 5% Cr, and finally decreases monotonically. A study of the phase composition of the Ni-Cr-Al system showed that up to 30 wt. % Cr the system contains the compounds NiAl_3 and Ni_2Al_3 . An increase in the chromium content of the alloy leads to the formation of two new phases equivalent in microhardness to the compounds Cr_4Al_9 and CrAl_4 . An

✓A proposed load test for the evaluation of the working capacity of patients with hepatic disease. Milos Faskati, Zdeňka Marešová, Pavel Fossati, und Milada Ilavácková (III. interní klin., Prague). *Casopis Lékařů Českých* 93, 713-21(1984).—Watson's (*C.A.* 39, 2086) modification of the Ehrlich aldehyde reaction was used for the estn. of urinary urobilinogen (I). On the first day of the test, I excretion was detd. before and after food intake. On the next day phys. exercise (14 km., 3.5 hr. walk) was applied. The reproducibility of the daily excretion curves was satisfactory in the absence of jaundice. In normal persons the I level falls or remains practically unchanged under the influence of the walk; in hepatic impairment there is a rise. Some chem. observations on the nonspecificity of the Ehrlich reaction are also reported. *Ivo M. Hajš*

Fusani, Milos

C L E U II

V Clinical significance of the urobilinogen excretion test.
Zdenka Marešová, Milos Fusani, Felix Mysa, and Pavel
Fusani (II. internal clin., Prague). Casopis Lékářů
Českých 93, 785-95(1954).—The urobilinogen (I) excretion
test (cf. preceding abstr.) was applied to 110 patients with
hepatic or biliary tract disease. Patients with cholecyto-
pathies did not differ appreciably from healthy persons. In
hepatic or subhepatic lesions the excretion of I was in-
creased at rest, and increased more after exertion. The
test yields information on the state of compensation. In
the posthepatitis fatigue syndrome the curves are consider-
ably raised after work. In hepatic lesions of a cirrhotic
character the elimination of I after meals showed a delayed
max. I. M. H.

A simple method for the estimation of inulin in the blood and the urine. Milos Fassati, Otto Kuchel, and Vladimir Pucovský (III. Intern. Klin., Prague). *Casopis Lékařů Českých* 94, 1130-41 (1955).—The method of Higashi and Peters (*C.I.*, 44, 6471c) has been modified. One ml. plasma or 1 ml. dild. urine is used. It is not necessary to cool with ice when adding the acidic FeCl_3 soln. to the inulin-resorcinol mixt., but stirring during the addn. and subsequent heating is necessary. It is preferable to use 77-77.5° for the heating of the mixt., as the color yield is less temp. dependent at the lower temp. It is advisable to run a standard with every series of samples. Correction is made according to the reagent and plasma or urine blank. The limit of this method were $10-00 \pm 2.4$ mg.%. Harrison's method (*C.I.*, 36, 2378^a) yielded practically identical results in clearance studies. It can be used for dogs, cats, and man. L.M. Haix

poznaní posthepatitických stavů. A contribution to the evaluation
of post-hepatitic conditions ČAS. LÉK. ČES. 1956, 95/6 (155-156)
The elevation of the urobilinogen level of the urine following physical work (charac-
teristic of the post-hepatitic fatigue syndrome) is chiefly due to the elevation of
stercobilinogen and not of mesobilirubinogen. Consequently this elevation in the
post-hepatitic syndromes might be considered to be in accordance with Baumgar-
tel's theory as a haemolytic state. This is confirmed by the fact that in some
cases the physical work is followed by a marked increase of the blood bilirubin
level even in cases where at rest the bilirubin level had been only slightly in-
creased (1.4 - 3.0 mg./100 ml., by Jendrassik-Grof's method or within normal
limits. In 15 healthy controls no bilirubin increase was found after physical work.

"Renal Excretion of Urobilinogen."

Prague, Casopis Lekaru Ceskych, Vol 105, No 24-25, 17 Jun 66, pp 640 - 645

Abstract /Authors' English summary modified: The excretion was studied in a short term experiment under varying degrees of diuresis. In patients with cirrhosis or hemolytic states urobilinogen was excreted in the same way as croatinine. In febrile patients no correlation of the two was found. 12 Figures, 9 Western, 9 1/1 Eastern, 1 Japanese reference. (Ms. rec. Aug 65).

"Dehydroepiandrosterone in Chronic Hepatopathies."

Prague, Casopis Lekaru Ceskych, Vol 105, No 32, 15 Aug 66, pp 855 - 856

Abstract /Authors' English summary modified: Investigation of the excretion of 17-KS fractions in 42 hepatic patients revealed a markedly selective reduced excretion of DHA. Relationship between the excretion of DHA in chronic liver disorders and the inhibitory effect of DHA on glucose-6-phosphate dehydrogenase is evaluated. 2 Tables, 9 Western, 2 Czech references. (Manuscript received Sep 65.).

Fassati, Pavel.

CZECH

✓ A proposed load test for the evaluation of the working capacity of patients with hepatic disease. Miroslav Fassati, Zdeňka Marclová, Pavel Fassati, and Milada Hlaváčková (III. interní klin., Prague). *Casopis Lékařů Českých* 93, 713-21 (1954).—Watson's (C.A. 39, 2080) modification of the Ehrlich aldehyde reaction was used for the estim. of urinary urobilinogen (1). On the first day of the test, 1 excretion was detd. before and after food intake. On the next day phys. exercise (14 km., 3.5 hr. walk) was applied. The reproducibility of the daily excretion curves was satisfactory in the absence of jaundice. In normal persons the I level falls or remains practically unchanged under the influence of the walk; in hepatic impairment there is a rise. Some chem. observations on the nonspecificity of the Ehrlich reaction are also reported. Ivo M. Halík

FASSATI, PAUL

C 2 & C 11

Clinical significance of the urobilinogen excretion test.
Zdeňka Marešová, Miroslav Fassati, Felix Myšoš, and Pavel
Farský (III. internal klin., Prague). Časopis Lékařů
Českých 93, 785-95 (1964).—The urobilinogen (I) excretion
test (cf. preceding abstr.) was applied to 110 patients with
hepatic or biliary tract disease. Patients with cholecysto-
pathia did not differ appreciably from healthy persons. In
hepatic or subhepatic lesions the excretion of I was in-
creased at rest, and increased more after exertion. The
test yields information on the state of compensation. In
the posthepatitis fatigue syndrome the curves are consider-
ably raised after work. In hepatic lesions of a cirrhotic
character the elimination of I after meals showed a delayed
max.

TITLE: Study of the shock wave of the Tungus meteorite from the associated forest destruction

SOURCE: AN SSSR. Komitet po meteoritam. Meteoritika, no. 24, 1964. Trudy* Desyatoy Meteoritnoy konferentsii v Leningrade 29 maya - 1 iyunya 1962 g., 112-128

TOPIC TAGS: meteorite, Tungus meteorite, shock wave

ABSTRACT: The radial flattening of the forest in the area of the explosion of the Tungus meteorite is the most reliable criterion for study of the propagation of the shock wave accompanying the explosion. The forest flattening has been investigated repeatedly on the ground and from the air and a considerable body of literature has accumulated concerning the phenomena, parts of which are reviewed in this paper. Data from the expeditions of 1960 and 1961 are discussed in the greatest detail; the methods applied to study of the forest flattening are becoming increasingly sophisticated. Emphasis in this article is on statistical analysis of data collected over the 2,000-km² area of forest flattening. New topographic

surveys and aerial photography have facilitated the investigation. Data are available for 580 points throughout the area; in the latest expedition a grid was laid out and azimuths of fallen trees measured carefully in the sample areas. A general description of the area of flattening is followed by a statistical analysis of the forest destruction. Particular attention is given to the central area and a study of the influence of relief on the degree of destruction. Fig. 1 of the Enclosure shows the flattening of the forest in the area of falling of the meteorite. Orig. art. has: 25 formulas, 11 figures and 1 table.

TITLE: Some results of studies of the problem of the
Tunguska meteorite

PERIODICAL: Geologiya i geofizika, no. 1, 1963, 111 - 123

TEXT: A Composite Independent Expedition (CIE) was organized
in 1959 and a number of scientific workers and engineers from
institutions of Tomsk, Moscow, Novosibirsk and other towns
participated in it. The aim of this expedition was to carry out
a composite study of the region of the fall of the meteorite.
Field work was carried out in 1960 together with a Moscow
expedition directed by V.A. Koshelev. There was an expedition
in the summer of 1961 organized by the Komitet po meteoritam
AN SSSR (Committee for Meteorites of the AS USSR) under the
direction of K.P. Florenskiy. The CIE was a part of the latter
expedition. Parallel field work was carried out during 1959-1961.

by the Committee for Meteorites (B.I. Vronskiy - 1959-1960 and A.V. Zolotov - 1959-1961). The present paper reviews briefly the results obtained by the CIE and compares them with those obtained by other workers. A chart is reproduced showing the marsh and woodland distribution and magnetometric profiles in the neighbourhood of the epicentre. It was found that the marshes were apparently natural formations, unaffected by the fall but there were some arboreal features indicating the effect of the fall on trees. A study was made in 1960 of the felling of trees as a result of the fall of the meteorite. Analysis of these data showed that the height at which the meteorite exploded was 10.5 ± 3.5 km. Magnetometric searches revealed the absence of major magnetic losses. Other studies revealed a region with enhanced concentration of Ni, Co and Mo in the soil and Ce, La, Y and Yb in the wood ash. This region was 2-6 km N.W. of the epicentre. A further series of measurements was concerned with the residual radioactivity in the region. Previous conclusions regarding the increase in radioactivity near the epicentre, as compared with greater distances, were not confirmed. It is suggested that the

earlier measurements revealed traces of fall-out due to American nuclear tests in 1958. Analysis of these and other published data leads the authors to suggest the following working hypothesis. In the middle of June, 1968, the Earth passed through a cosmic-dust cloud which entered the atmosphere and sedimented between 55 and 65° N. On reaching the lower layers of the atmosphere, dust particles gave rise to anomalous airglow and development of noctiluscent clouds at isolated points in Europe between June 22 and 29. The amount of dust was not, however, too great and hence the optical anomalies associated with it were localized and there was no change in the polarization of the day sky. In the morning of June 30, the Earth entered the part of the cloud containing large dust-particle clusters and the penetration of these clusters into the lower layers gave rise to a change in the polarization and the appearance of a solar halo and noctiluscent clouds. At the same time, a major meteoritic body entered the atmosphere. The resistance experienced by the body (dense swarm of particles) increased rapidly at the boundary of the troposphere with the result that the body was decelerated and the available magnetic

energy was converted into the energy of the explosion. This hypothesis is not fundamentally different from that put forward by V.G. Fesenkov (cometary hypothesis). It is suggested that the differences may be of terminological origin. This must be investigated further. There are 1 figure and 1 table.
